SpaceX Starship Simulator:

By Thomas Palmer

Scientific Purpose:

Hundreds of objects are sent into space, and millions of dollars are wasted each year through failures (Aerospace CSIS 2020). *StarshipSim* can be used by potential customers of SpaceX to accurately simulate whether their payloads can withstand the immense stresses an object is subjected to when travelling into space without leaving the ground. Before manufacturing, an individual part, system or the entire vehicle can be simulated 100's of times with no extra cost. Satellites, Space Stations and Spacecraft can all be tested.

StarshipSim is designed for the SpaceX Starship launch vehicle only, which is currently under development by SpaceX, with an orbital test expected in the coming weeks. This program will reduce the likelihood of catastrophic incidents, and could save billions of dollars in damages.

StarshipSim demonstrates the fundamental laws of physics, thermodynamics, fluid dynamics and drag to achieve high accuracy in the simulation of travelling through the atmosphere, getting into orbit and speeding towards other celestial bodies.

Using the Program:

After loading, a few questions will appear on the screen. After answering, the vehicle will be ready to launch. It will automatically set itself on a trajectory to achieve a stable orbit, and from there another program is used to simulate interplanetary flight. A detailed method is available under the *Methods* section.

Loading the Program:

The program runs in Python 3.7 using the PyPi modules: Pygame, Thorpy, OS, and EasyGui.

To open the demonstration video, access Google Drive, open *StarshipSim* and either use the built-in or third-party video player available on the device.

Entering Payload Specifications:

The first question is 'What is the Payload Weight in kilograms?'. This sets the weight of the product that the consumer wishes to travel into space. The next question is 'What is the Payload G-Force Rating?'. This sets the gravitational force stresses the payload can withstand before critical failure. The final question is 'What is the temperature rating in celsius?'. This sets the temperature that the payload can withstand before critical failure. Submit answers by clicking Enter. After completing these questions, the vehicle is ready to launch.

Controls:

By pressing the UP arrow key, if all prior steps were completed properly, then the vehicle will begin to launch. The movement, time and stress statistics are shown in the bottom left-hand corner of the screen. The vehicle will set itself on a suitable trajectory to achieve orbit. From there, transferring to the program *interplanetary.py* will enable the vehicle to travel to either the Moon or Mars.

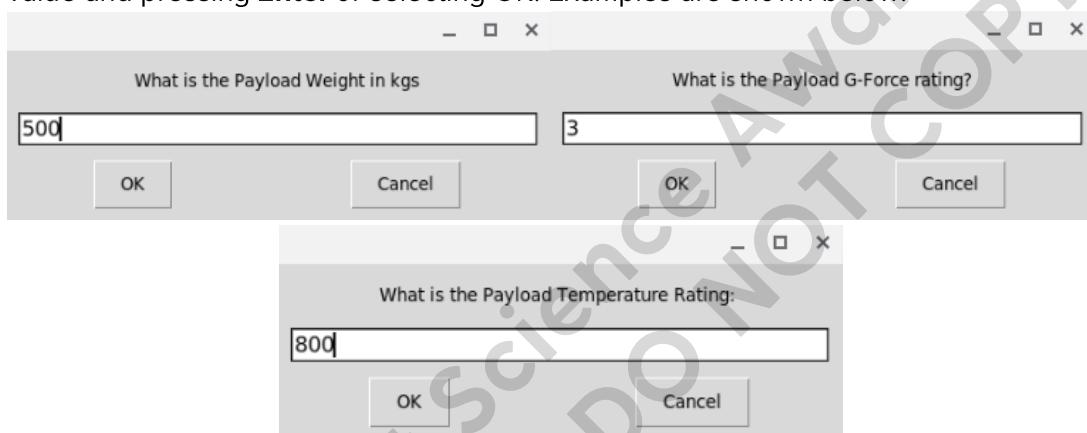

If the payload ratings were exceeded, then the mission will end in a failure and the rocket will explode. This shows that the payload is not robust enough to withstand the stresses of the mission.

Method:

1. Load StarshipSim2.py using instructions under “**Loading the Program**”.

2. Answer the three questions ‘What is the Payload Weight in kilograms?’, ‘What is the Payload G-Force Rating’ and ‘What is the temperature rating in celsius?’ by entering a value and pressing **Enter** or selecting OK. Examples are shown below.

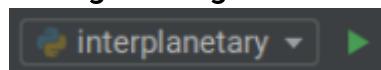

3. The flight data will need to be recorded manually by the user. An automated system is currently under development.
4. To ignite the first stage of the vehicle click the **UP** arrow key
5. Notice in the **left-hand corner** of the screen that vehicle data is displayed in real-time.

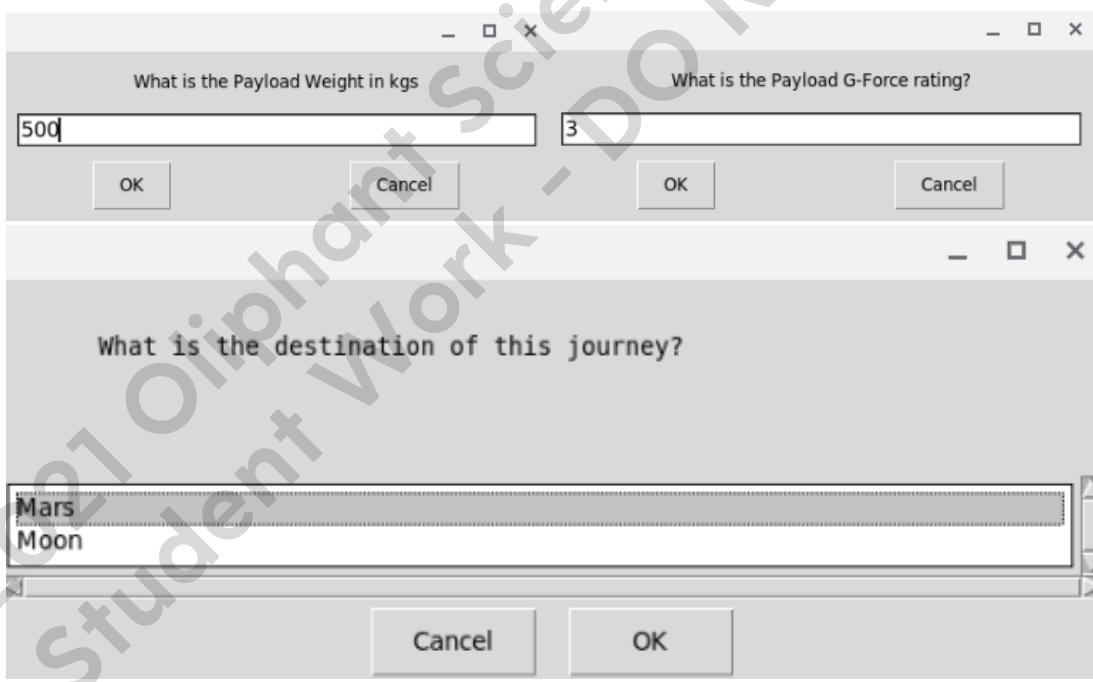

6. The vehicle will steer itself on a predetermined course utilising data from the SpaceX Falcon Heavy vehicle launches.

7. To continue on for interplanetary travel, load interplanetary.py using instructions under “[Loading the Program](#)”.

8. Answer the questions displayed on the screen, and select your destination.

9. Press the **UP** arrow key to ignite the interplanetary stage.

10. The layout of the screen is nearly identical to the orbital program.

- Once finished on either program, click **esc** to exit.

The Program:

The programs were written in Python 3.7 and a copy of the code is displayed below.

StarshipSim2.py

```

screen.blit(starship, (x, y))

box.blit()

pygame.display.update()
```

Acknowledgment:

James Palmer clarified a few elements within the program, but the entire program was written by Thomas Palmer.

Video Simulation:

The video enters payload characteristics similar to a small space station or a space telescope. If the G-Force or Temperature ratings were to be exceeded by simulated figures, then the mission would be unsuccessful, characterised by an on-screen explosion.

The video first showed a payload weight of 50 tonnes, a G-Force rating of 3G, and a temperature rating of 2000 degrees celsius. Then the **UP** arrow key was pressed for ignition. After attaining orbit, the program was shut off by pressing the **esc** key and `interplanetary.py` was loaded. From there similar characteristics were entered along with the destination, and a time warped simulation was shown. The video concluded by shutting off `interplanetary.py` by pressing the **esc** key.
